Online Slurry Air-content Determination and Analysis (OSADA) Technology
for Oil Sand Development at Syncrude

by

Houshang Ghazi

A thesis submitted to the Faculty of Graduate Studies and Research in partial
fulfillment of the requirements for the degree of Master of Science

In

Mining Engineering

Department of Civil and Environmental Engineering

Edmonton, Alberta

Spring 2003

University of Alberta

Faculty of Graduate Studies and Research

The undersigned certify that they have read, and recommend to the Faculty of Graduate Studies and Research for acceptance, a thesis entitled *Online Slurry Air-content Determination and Analysis (OSADA) Technology for Oil Sand Development at Syncrude* submitted by *Houshang Ghazi* in partial fulfillment of the requirements for the degree of *Master of Science in Mining Engineering*.

ABSTRACT

At Syncrude, slurry pipeline hydrotransportation is a means for reducing oil sands ore haulage cost by dump trucks. A greater understanding and knowledge is required in this area to optimize an efficient hydro-transport system.

The challenge in this project (thesis) was to detect the amount of air holdup within a flow of water, air mixture and solid (two and three phases) in a test loop, in the Syncrude slurry pipeline, and in an experimental bubbling water column, by means of the sound waves.

A relationship was established between the air content of the flow and its resonance frequency caused by the proper external audible sound wave (active means). Also, the generated audible noise spectrum of the slurry pipeline during the operation was measured and recorded (passive means). Its existing natural resonance frequencies were identified and then were related to its amount of air content.

Key words: Air Content, Bubble Holdup, Dispersed Phases, Audible & Ultrasound,
Resonance

ACKNOWLEDGEMENT

The author wishes to recognize the following colleagues for their advice and assistance in this project, and express his gratitude to them. During the course of this thesis the author worked, and communicated frequently with Dr. Julian Coward (Syncrude Research), Dr. Jozef Szymanski (U. of Alberta), and some others. For the assembly of the lab experimental piping and setup of its required equipment at the Pilot Plant of Syncrude Research Centre (SCR) in Edmonton, the author was assisted by Dr. Julian Coward, and Westway Contractors Limited workers, in particular Wayne Smiley.

The main financial support for this project was provided by the Alberta Energy Research Institute (AERI), COURSE Program 1361, University of Alberta (School of Mining and Petroleum Engineering), and Syncrude Research Centre (SRC). The author wishes to recognize Dr. Catherine Lareshen (AERI) for her guidance and advice in the preparation of the required reports to (AERI). The author also wishes to express his appreciation for space provided for the experimental test setup at the pilot plant, and for the office to work in at SRC.

Above all the author wishes to dedicate this work to his loving wife Minoo, and son Hooman. The author recognizes and appreciates their encouragement, patient, help and cooperation during his years of study for his M. Eng. degree at mechanical engineering and for M.Sc. degree at mining engineering of University of Alberta.

$\lambda_1 :$	(E4-1)	First harmonics wave length (m)
$\nu :$	(E4-11)	Kinematic viscosity (m ² /s)
$\theta :$	(E5-5)	Angle of incident (radian)
$\rho :$	(E5-5)	Density of medium (kg/m ³)
$\rho_e :$	(E2-1)	Effective density (kg/m ³)
$\rho_m :$	(E4-2)	Mixture density (kg/m ³)
$\rho_s :$	(E5-5)	Plate surface density (kg/m ²)
$\tau :$	(E5-4)	Sound transmission coefficient

CHAPTER 1:

GENERAL INTRODUCTION

At Syncrude mine sites, located about 30 km north of the town of Fort McMurray most of the ore is now transported by hydrotransportation pipelines. Currently there are four major hydrotransport pipelines at Syncrude sites. One pipeline is located at EAPS (Extraction Auxiliary Production System), two pipelines at North Mine, and one at Aurora Mine. The typical operating rates for the systems are about 4000 to 8000 t/hour of oil sand and with the slurry flow rate of 0.7 to 1.2 m³/s. The diameters of the pipelines range from 0.6 to 0.8 m, and their lengths from 2.5 to 4.3 km. Transported oil sand slurry goes into the processing plant. There bitumen is floated off the slurry, and then processed into a marketable synthetic crude oil. Currently daily Syncrude crude oil production is about 250,000 Bbls/day (39,750 m³/day). That amounts to about for 12% of Canada's current crude oil consumption.

The Aurora Mine will use the next generation of Surface Mining and Extraction Technology

Figure 1-1

1.1: PUMP PERFORMANCE WITH GAS IN SLURRIES

Air and gas can get into the slurry pipelines in a number of different ways. The tar sand feed may contain some air in the pores of lumps at the time it is mixed with hot water. Air and gas may be lost or gained in the pump box, especially if the flow is very turbulent. Finally some air and gas may be liberated from the bitumen as the oil sand mixes with the hot water.

The detrimental effect of gas existence in the fluid on pump performance has been known for sometime. Not much data about the effect is available in the literature. The effect of air or gas content in a fluid on pump performance is fairly complicated. It is generally known that the effect depends on the volumetric proportion of the gas in the slurry, type and size of pump used, the type of gas, the type of fluid, the pump flow rate, the fluid temperature, and the pressure at the pump inlet and outlet. Thus as the pressure of the flow increases, the effect would be lower. In general, the pump performance is degraded when there is gas in the fluid, particularly at higher flow rates and low pump inlet pressure.

(Stepanoff, 1957) has indicated that for a 10-inch (25 cm) volute pump at relatively high flows and at ambient suction pressure, a 2% by volume air in water can give an efficiency ratio degrade to about 85% (Fig. 1-2). Under the same condition and if the air volume was increased to 4%, then the efficiency ratio may be degraded further and that was down to 70%. (Florjancic, reference in Herlich) has measured both efficiency and head ratios to be at 85% and 0.85, with air addition of 4% by volume (measured at the inlet pressure of 250 kPa). For the 5% air volume at the same inlet pressure, the efficiency ratio was down to 79% and the head ratio was degraded to 0.75 only (Fig. 1-3). Better pump performance was measured at higher inlet pressures, even with the same volumetric air contents at the pump inlet.

Figure 1-2

Figure 1-3

Normally in the oil sand slurry pipelines, the amount of gas (air) in the slurry is expected to be relatively small with only a few volume percentages. But even this small gas amount may affect the overall pump efficiency to some degree, and result in increased power draws in the pipeline system. In the oil sand slurries, on the other hand, some gas (air) is required to improve the bitumen recovery at the processing plant. There is therefore a trade-off between the needed amount of air for bitumen recovery and the degrading of the pump efficiency.

1.2: GAS CONTENT MEASUREMENT IN SLURRIES

The existing methods for measurement of gas content in slurries include the following:

1. Finding out what gas content of slurry is by sampling and analyzing it. The sampling is not an easy task and care should be taken to preserve the gas content of the taken sample. The solid and bitumen in the slurry would complicate the measurement. The method is not online or continuous.
2. Measuring gas content by means of nuclear density gauges. The gauges basically measure the average fluid density. In the case of existing gas content, the density reading would be lower than gas-free fluid. The method for measuring slurries is very difficult because the density of the flow varies continuously, and the gas-free fluid density could not be easily determined.
3. Estimating gas content of slurry based on the compressibility of the slurry. A working slurry pipeline could be shut down; the ends sealed off by shut-off valves, and the pipeline pressurized by water. The rise in pressure can then be determined from the derived fluid compressibility. In the past, Syncrude has used this method on some experimental pipeline loops. But it is not easy to carry out the experiment on a commercial pipeline.

4. Determining gas content in the slurries through the use of pump efficiency data.
The pump efficiencies are affected by gas content. The solid content of slurry may also degrade efficiency and may mask the effect of gas (Coward, 1997).
5. In a pipeline, the gas content may be estimated by measuring the speed of sound as it was the intention of this thesis.

CHAPTER 2:

LITERATURE SURVEY

2.1: GENERAL CHARACTERISTICS OF FLUID MOTION IN ROUND PIPES

(Hildebrandt, 1982) explains that, the acoustic properties of round pipes with respect to the viscous and inertial forces of the fluid based on the (Rayleigh, 1945) work was investigated by him. To find out the behavior of a fluid motion in a round pipe, the extreme cases at low and high frequencies were looked at.

At the low acoustic frequencies or when the pipe diameter is very small, the viscous property of the fluid dominates the flow behavior (Hildebrandt, 1982). The mean velocity of the fluid is in proportion and in phase with the pressure gradient of the fluid. At the pipe wall, the flow velocity profile is zero (boundary condition) and at the center of the pipe, the fastest. The velocity profile shapes as an approximate parabola.

In the case of dealing with the high acoustic frequencies, the fluid motion will be affected by two factors:

The first factor is the inertia of the fluid. If the inertial forces dominate over the viscous forces, then the fluid motion lags behind the pressure gradient. If the pressure gradient varies harmonically, and the frequency increases, the velocity lag will approach 90° . Also the velocity profile flattens and the peak velocity decreases with increase in frequency. This physical situation is identical to a damper-mass system in the model (Fig. 1-3). In this model, for a constant applied force, the amplitude of vibration decreases as the frequency increases.

Figure 1-5: Damper-mass model for inertia of fluid

The second factor influencing the fluid motion is the heat conduction. At high frequencies, the heat of the fluid is not transmitted fast enough to the piping wall. As a result, the temperature of the fluid is not constant (non isothermal, $\Delta T \neq 0$). This in itself causes three following effects:

- a) Speed of sound will approach the adiabatic speed of sound (for $\Delta Q = 0$), which is 343 m/s for air.
- b) Since the piping wall has a lesser influence on the temperature of the fluid, there will be a significant temperature difference developed between the wall and the fluid at the axis direction of the pipe. As a result, the viscosity of the fluid will no longer be constant.
- c) Dissipation effect comes into account, occurring in the fluid in the form of thermal processes. Even at high frequencies, viscous forces dominate the dissipation of the wave energy.

(Biot, 1956) developed a function to explain the interaction of the viscous and the inertial forces in the narrow channels and round pipes. His function was related to the momentum balance as shown. Based on that, the fluid velocity was taken to be constant across the pipe and was assumed to be equal to U :

$$-\frac{\partial P}{\partial X} = \rho_{e|k=0} \overline{U'} - F_{(k)} R_{|k=0} \overline{U} \quad (\text{E2-1})$$

That may be written as:

$$-\frac{\partial P}{\partial X} = \rho_e \overline{U'} - R \overline{U} \quad (\text{E2-2})$$

Where:

$\overline{U}$: Complex mean velocity, averaged across the pipe at $t = 0^\circ$ and $t = 90^\circ$ in the cycle

$\overline{U'}$: Time derivative of $\overline{U}$ along the pipe

ρ_e : The effective density

R : The resistivity ($\text{Kg/m}^3\text{s}$)

P : Pressure

It can be expected that the effective density and resistivity must vary with the change in frequency caused by contrasting the fluid motion characteristics at low and high frequencies. As an example, the damper-mass model shows that at high frequencies the magnitude of the velocity decreases (inverse relation). This indicates that the resistivity increases with frequency (direct relation). These properties that are the functions of frequency are also dependent on the type of pipe used.

2.2: CURRENT FORMULATION of CONSERVATION and BALANCE EQUATIONS for MULTIPHASE FLOW MODELING

There has been a considerable advance in the development of useful models for two-phase flows (Dobran, 1984). On the other hand, similar development for the three-phase flows has not been as rapid. The multiphase flow analysis is difficult because of their finite interfacial area. This fact has led to the diverse modeling approach, which is based on a continuum practice. (Dobran, 1984) wrote: “The conservation and balance equations of multiphase flows constructed in this manner are either postulated (Drumheller, 1980) (Sha, 1978), or they are obtained by an application of suitable averaging of the macroscopic field equations of each phase (Drew, 1971) (Marle, 1982).” Both approaches have deficiencies. The first one lacks a strong physical justification. The second one lacks reconciliation between the different levels of description. The modeling of multiphase flows is based on one of the following approaches:

- a) Using the single-phase multi-component mixtures equations and extending it to multiphase mixtures.
- b) Averaging the instantaneous field equations of each phase over the needed time and space.

After an elaborated discussion (Dobran, 1984) explains each modeling approach and its limitation. He finally concludes that: “The theory of multiphase flows is in an infancy of development.” And, “Clearly, while considerable progress has been made in the formulation of conservation, balance and constitutive equations for multiphase flows, much more work remains to be done in the future through both analysis and fundamental experiments.”

CHAPTER 3:

GENERAL APPROACHES FOR THE THESIS

This thesis investigated a problem that involved exploring two different sound wave approaches, in order to determine the air (gas) content of the tar sand slurry in the pipeline. For the first approach, an audible sound wave was transmitted and linked to the resonance frequency of the slurry pipeline, to determine the amount of its air (or gas) content (active method). For the second approach, the methodology consisted of recording the flow noise of the slurry pipeline and relating its audible noise resonance to the air (gas) content in the flow (passive method). Some previous work (Ghazi, 1998) was done on a similar problem by conducting the pressure wave tests within the multiphase fluid loop.

CHAPTER 4:

RESONANT FREQUENCY TESTS

4.1: INTRODUCTION

If a sound wave (or pressure wave) is sent across the diameter of a pipe then:
First harmonic of its resonance will occur as shown in (Fig. 4-1):

Figure 4-1

Schematic of First Harmonic across the Pipe

4.2: THEORETICAL DEVELOPMENT

In Fig. 4-1 for fluid harmonic:

$$\lambda_1 = 2D$$

$$f_1 = C / \lambda_1 = C / 2D$$

$$C = 2D f_1 \quad (\text{E4-1})$$

λ_1 : First harmonics wave length, m

D : Diameter of the pipe, m

f_1 : First harmonics frequency, Hz

C : Speed of sound in the slurry, m/s

Thus, if first harmonic resonance frequency of slurry content in the pipe is determined, the speed of sound in the pipe can be found (Serway, 1982, Coward, 1997&1998). Also It has been long time known that the speed of sound in the materials (C) including fluids may be calculated using the bulk modulus (B) and the density (ρ) of the material:

$$C^2 = B / \rho$$

Further the speed of sound in a multi phase slurry mixture within a pipe may be related to its different contents (air, liquid, solid), based on the following formula derived by (Shook, 1976).

$$1/C^2 = \rho_m [\alpha_1 / B_1 + \alpha_2 / B_2 + \dots + D / E_p t] \quad (\text{E4-2})$$

ρ_m : Mixture density, Kg/m³

α : Volumetric proportion

D : Pipe outer diameter, m

t : Wall thickness, m

B : Bulk modulus of material, Pa

E_p : Elastic modules of pipe, Pa

The air content can then be determined by finding out the speed of sound in slurry. To derive the above formula (Shook, 1976) assumed that the distribution of the dispersed phase was uniform. He also noted that: "Dispersed gases are presumed to obey some equilibrium pressure-volume relationship during pressure changes, such as that for ideal

gases in isentropic processes. Surface or interfacial effects do not seem to be important because good agreement with experimental results is observed.”

4.2.1: LITERATURE SURVEY

4.2.1.1: Acoustical Waves in a Homogeneous Mixture

(Wijngaarden, 1972) considered a homogeneous fluid with only some small gas bubbles in it for modeling. He assumed the process was to be isothermal (constant temperature), with possible compressibility of the bubbles in it. The other assumed conditions were to consider the bubbly character of the gas content, plus to consider the movement of gas and fluid should take place at the same velocity. For the properties of gas and fluid, “g” and “f” subscript were chosen, respectively. Let “ β ” to be the volume of gas within a unit volume of the bubbly fluid.

$$\beta = \frac{V_g}{V_f + V_g} = \frac{V_g}{1} = V_g \quad (\text{E4-3})$$

The density of the mixture ρ would be:

$$\rho = \rho_f(1 - \beta) + \rho_g\beta \quad (\text{E4-4})$$

The mass of the gas in the unit mass of the mixture would be constant.

$$\frac{\rho_g\beta}{\rho_f(1 - \beta)} = \text{constant} \quad (\text{E4-5})$$

Also p mixture is equal to p_g in the gas which is itself (for constant temperature), in proportion to ρ_g . Therefore:

$$\frac{p\beta}{\rho_f(1 - \beta)} = \text{constant} \quad (\text{E4-6})$$

To find the sound velocity c , he wrote:

$$c^2 = \frac{dp}{d\rho} \quad (\text{E4-7})$$

By substitution from equation (E4-4):

$$\frac{1}{c^2} = \frac{d\rho}{dp} = (1 - \beta) \frac{d\rho_f}{dp} + (\rho_g - \rho_f) \frac{d\beta}{dp} + \beta \frac{d\rho_g}{dp}$$

With respect to equation (E4-7), and:

$$c_f^2 = \frac{d\rho_f}{dp}$$

$$c_g^2 = \frac{d\rho_g}{dp}$$

And neglecting $\rho_g^2 c_g^2 / \rho_f^2 c_f^2$ with respect to unity, then:

$$\frac{1}{c^2} = \frac{(1 - \beta)^2}{c_f^2} + \frac{\beta^2}{c_g^2} + \frac{\rho_f \beta (1 - \beta)}{p} \quad (\text{E4-8})$$

That shows that unless β is very close either to zero or unity, the speed of sound in the bubbly fluid will be lower than the speed of sound in the pure gas. For the other β magnitudes equation (E4-8) may be approximated to:

$$c^2 = \frac{p}{\rho_f \beta (1 - \beta)} \quad (\text{E4-9})$$

As an example, for $\beta=4\%$, and at atmospheric pressure, calculated c is only 50 m/s, which is much lower than either c_f or c_g .

4.3: METHODOLOGY AND RESEARCH OBJECTIVES

For this stage of the work the intention was to conduct an experiment to determine the resonance frequency of the proposed multiphase pipe loop that may be related to its amount of air content. That may be done by transmitting a proper range of the audible sound wave on one side of the pipe. The sound wave would travel across the diameter of the pipe that is perpendicular to the axes of the pipe and flow direction. Then amplifying, and displaying the received signal from the other side of the pipe and by means of an oscilloscope would indicate the resonance frequency of the pipe. The pipe may contain a flow of water, some low percentage of air (gas), and some solid particles in different test stages.

4.4: APPROACH FOR THE RESONANT FREQUENCY TESTS

A proper piping loop was designed and set up for the intended experiments. Then after the loop was refilled and a measured percentage volume of air content within the fluid was set up, an audible sound wave was transmitted at one side of the pipe, and the received signal from the other side was displayed on an oscilloscope. By investigating the received signal, the resonance frequency of the pipe and its content was identified and became interrelated to the fluid's air content percentage in the fluid.

4.5: TEST PROCEDURE

4.5.1: TEST SETUP

A rectangular shape closed loop of 38.1 mm diameter (1.5") clear PVC pipe and fittings was built. The overall length of the loop was about 9 meters. A centrifugal sewage type pump was part of the loop and was to be located at the corner of the loop (CP) (Figure 4-2). The pump was to handle slurries (particles) and was capable of maintaining a turbulent flow for a proper homogeneous blend. For that to happen, velocity of the flow had to be somewhat between 2.2 and 1.7 m/s, with respect to the Reynolds number and roughness of the pipe. For this project it was decided to have more than 3 m/s flow velocity design in order to select the pump. The selected 746 w (1 hp) pump had:

$$Q = 0.00379 \text{ m}^3/\text{s} \text{ capacity} = 3.79 \text{ liters/s} = 60 \text{ gpm}$$

$$H = 7 \text{ m head} = 10.2 \text{ psi}$$

$$\text{Length of the loop, } L = 9 \text{ m}$$

$$\text{Pipe diameter, } D = 38.1 \text{ mm} = 0.0381 \text{ m}$$

$$\text{Density of water, } \rho = 1000 \text{ kg/m}^3$$

$$g = 9.81 \text{ m/s}^2$$

$$V = Q / A = (0.00379 \text{ m}^3/\text{s}) / (\pi)(0.0307 / 2)^2 \quad (\text{E4-10})$$

$$V = 5.12 \text{ m/s}$$

$$Re = DV / \nu \quad (\text{E4-11})$$

ν : Kinematic viscosity

ν : For water at 25 C is $0.893 \times 10^{-6} \text{ m}^2/\text{s}$, from table 4-1

$$Re = (0.0307 \text{ m})(5.12 \text{ m/s}) / (0.893 \times 10^{-6} \text{ m}^2/\text{s}) = 2.18 \times 10^5$$

$$Re = 2.18 \times 10^5 >> 2400$$

The result indicates that the flow would be very well within the turbulence range (Figure 4-2).

To find out the pressure drop within the designed loop:

$$P_1/\rho g + Z_1 + (V_1)^2/2g = P_2/\rho g + Z_2 + (V_2)^2/2g + H \quad (\text{E4-12})$$

$Z_1 = Z_2$ As there is no elevation change between the two points

$$(P_1 - P_2)/\rho g = H \quad (\text{E4-13})$$

And as:

$$H = f(L/D)(V^2/2g) \quad (\text{E4-14})$$

So:

$$(P_1 - P_2)/\rho g = f(L/D)(V^2/2g) \quad (\text{E4-15})$$

For PVC pipe, if the relative internal surface roughness is $e/D = 0.0003$, (Figure 4-2), then for Reynolds number 7.17×10^5 (5.12 m/s velocity), the resistance coefficient

$$f = 0.015$$

$$P_1 - P_2 = (0.015)(1000 \text{ kg/m}^3)(9/0.0307\text{m})(5.12 \text{ m/s})^2/2$$

$$P_1 - P_2 = 57.6 \text{ KPa} = 8.4 \text{ psi} \quad \text{Pressure drop expected around the loop}$$

Table 4-1: Kinematic Viscosities (ν) of Water and Air

Figure 4-2 Laminar, turbulent flow and Reynolds number

Figure 4-3 Experimental Tests Loop

Refilling and venting the loop was done through the bypass valves, pipes, and the side bucket (B). To drain the loop valve (D) was used to let off a specified amount of water. This amount was replaced by the air infiltrated into the pipe through valve (D) (Fig. 4-2).

4.5.2: WHAT WAS TO BE MEASURED?

As it was mentioned earlier in the objectives of the project, the resonance frequency of the pipe and its content was to be measured. The result then could be linked to the amount of air content within the flow.

4.5.3: REFILLING AND DRAINING THE PIPE LOOP SYSTEM

The system (Fig. 4-2) was to be refilled through an open bucket (B). The pump (CP) was to be used to direct any unwanted air to the bucket, gradually through the connection valve (BI). The complete refilled loop could be drained through the drain (D) valve into a measuring bucket. The purpose for this initially was to measure the exact volume of the loop. In order to introduce any desired percentage of the air into the loop, all that was required was a water-filled system by the amount of volume chosen. Afterward, air entered into the loop would be made to replace the drained water along the drain line.

4.5.4: HOW THE MEASUREMENT TOOK PLACE?

The system was started up with a measured volume of fluid and air, and run for a few minutes in order to obtain a proper turbulent blend, as well as to bring it to its steady state homogeneous fluid flow condition. At this point all the instruments for measurement were connected to the loop (Fig. 4-3) and were energized. The signal generator was set to the sine wave, and its knob was turned slowly to change its frequency. The generated sound was broadcast from the speaker (S), and passed through the PVC pipe and its moving fluid. The Piezoelectric pressure transducer (PT) received the sound signal through its conditioner, and sent it to the scope to display. The observation indicated that at the first resonance frequency, the displayed graph got excited and its width along the Y-axis broadened. At this time the corresponding frequency was recorded.

Fig. 4-4: Instrumentation Hook up for the Loon

As an example: For the 1.5" PVC pipe loop that is filled with 100% water, the speed of sound could be calculated by the Shook's equation as (Ghazi, 1998):

$$1/C^2 = \rho_m (\alpha_w / B_w + D / E_p t) \quad (E4-16)$$

Physical properties for some common materials are given in (Table 4-2):

Material	V _{sound} (m/s)	d (Kg/m ³)	Bulk Modu. (MPa)	Elast. Modu. (MPa)
Air	331	1.293	0.141662	
Bitumen	1350	995	1813.4	
Poly Ethylene	443	1050	206	
Water	1496	1000	2100	
PVC	1448	1400		2937
Quarts	5900	2200	36542	71705
Steel	5940	7840	160000	203395

Table 4-2: Physical properties for some common materials

(Baumeister 1978 , Lide 1991)

Note: Bulk modulus of elasticity of a fluid (B) (different from modulus of elasticity, E)

is the ratio of the pressure stress to the volumetric strain (its unit is Pa)

$$1/C^2 = (1000 \text{ kg/m}^2) [1/2100 \times 10^6 \text{ Pa} + (38.1 \text{ mm}) / (2.937 \times 10^9 \text{ Pa})(3.68 \text{ mm})]$$

$$C = 500 \text{ m/s}$$

For an amount of 0.1% (by volume) air content in the same 1.5" diameter PVC

(Polyvinyl Chlorine) pipe, the calculation would be:

$$1/C^2 = \rho_m (\alpha_a / B_a + \alpha_w / B_w + D / E_p t) \quad (E4-17)$$

$$\alpha_a = 0.001, \quad B_a = 0.14166 \times 10^6 \text{ Pa}$$

$$\alpha_w = 0.999, \quad B_w = 2100 \times 10^6 \text{ Pa}$$

$$D = 38.1 \text{ mm}, E_p = 2937 \times 10^6 \text{ Pa}, t = 3.68 \text{ mm}$$

$$\rho_m = \rho_a \alpha_a + \rho_w \alpha_w \quad (E4-18)$$

$$\rho_a = 1.293 \text{ kg/m}^3, \quad \rho_w = 1000 \text{ kg/m}^3$$

$$\rho_m = 1.293 \times 0.001 + 1000 \times 0.999 = 999.001 \text{ kg / m}^3$$

$$1/C^2 = 999.001 (0.001/0.14166 \times 10^6 + 0.999/2100 \times 10^6 + 38.1/3.68 \times 2.937 \times 10^9)$$

$$C = 300.84 \text{ m / s}$$

The calculation shows that the effect of a small amount of air content (0.1% by volume) on the speed of sound in the mixture of water and air flowing in the pipe is very dramatic; because it caused the speed to drop from 500 m/s down to 300.84 m/s.

In another example, for the 3.8 cm (1.5 inch) PVC pipe that was filled by volume percentage of 94.9% water, 5% beads (Polyethylene dyed with graphite), and 0.1% air, the speed of sound by the Shook's equation may be calculated as:

$$1/C^2 = \rho_m (\alpha_w / B_w + \alpha_e / B_e + \alpha_a / B_a + D / E_{pt}) \quad (E4-19)$$

$$\rho_m = \rho_w \alpha_w + \rho_e \alpha_e + \rho_a \alpha_a \quad (E4-20)$$

$$\rho_e = 1050 \text{ kg/m}^3$$

$$E_e = 206 \times 10^6 \text{ Pa}$$

$$\rho_m = 1000 \times 0.949 + 1050 \times 0.05 + 1.293 \times 0.001 = 1001.5$$

$$1/C^2 = (1001.5 \text{ kg/m}^3) [0.949/2100 \times 10^6 \text{ Pa} + 0.05/206 \times 10^6 \text{ Pa} + 0.001/0.14166 \times 10^6 + (38.1 \text{ mm}) / (2.937 \times 10^9)(3.68 \text{ mm})] = 1.1 \times 10^{-8}$$

$$C = 300.79 \text{ m/s}$$

That means the Time Of Flight (TOF) of sound wave across the pipe tee fitting (11 cm) will be somewhere between 0.2 to 0.4 milliseconds. The instrument was used to capture the signal for measurement was a piezoelectric pressure transducer. Its sensitivity was capable of handling the sound velocity of 500 m/s or even less.

The expected sound velocity within the air water mixture at the 1.5" PVC pipe loop may be calculated as below (Table 4-3):

Sound Speed PVC 1.5" Pipe (Air, Water) Shook

$B_a (P_a)$	1.4166E+05	D (mm)	38.1	$d_a (kg/m^3)$	1.293
$B_w (P_a)$	2.1000E+09	t (mm)	3.68	$d_w (kg/m^3)$	1000
$E_p (P_a)$	2.9370E+09

5	0.05	3.3911E-04	54.30

Table 4-3: Speed of sound in 1.5" PVC pipe

Using the data in the above table, the plot of theoretical resonance frequencies of the 38 mm (1.5") PVC pipe with air content in the 0% to 100% range (Figure 4-5) could be drawn. The expected sound speed through the fluid may be calculated by the Shook's equation (Ghazi, 1998). As the plotted graph demonstrates, the maximum resonance frequency of the pipe is 2272.36 Hz, which occurs at 0% air content. On the other hand, air content of 50% will result in the minimum resonance frequency of 108.7 Hz of the pipe.

Figure 4-5

4.6: EXPERIMENTATION

4.6.1: PIPING LOOP SET UP AND INITIAL EXPERIMENTATION

After the designed PVC piping loop was assembled, the loop was filled with clean tap water through its bucket (B)(Fig. 4-2). The pump that was selected had a 746 W (1 hp) three-phase motor. By using a Variable Frequency Drive (VFD) power supply, the pump could be run at various speeds and powers. Once the pump was running, the air bubbles were forced to enter the bucket (B) by throttling the (BBC) and (BI) valves moderately. Then the air bubbles were directed upward to the water surface with an elbow and nipple. The pump suction was designed to withdraw water from a lower port of the bucket, which would be bubble free (BO valve).

To remove all the air, a speed of 45 Hertz at the VFD was needed. The velocity of circulating water caused the movement of the bubbles from the clear PVC pipe loop and into the bucket (B). In about four minutes, all the bubbles in the loop were visually removed from the water and vented out through the bucket. At this point, no bubbles could be seen circulating through the clear PVC piping. Then, the bypassing valve at the bucket side (BBP) was opened up and the valves connected to the bucket were turned off (BI & BO).

For the three-phase fluid flow test (water, air and beads), some fabric screens were installed at the inlet and outlet piping to and from the bucket and at the drain valve (D), in order to entrap the beads within the pipe.

4.6.2: EXPERIMENTATION WITH THE FULL LOOP

The condition for the first test consisted of starting up the pump and throttling up its frequency to the maximum of 55 Hz. At this point the conditioner for the Piezoelectric transducers sensors (PS) (Fig. 4-2), which was battery operated, had to be turned on. It was also necessary to turn on the oscilloscope and to make the required adjustment at one of its input channels, because there was only one input signal.

To introduce a measured percentage volume of the air into the full loop, it was necessary to measure the volume of the moving part of the fluid in the loop. This was done by draining the water from filled loop and measuring it, as well as calculating the volume of the sections that were not drainable, such as the bottom half of the pump volute casing. As a result, the effective volume of the moving fluid within the loop was determined and found to be 14,230 cm³.

4.7: TEST RESULTS AND INTERPRETATION

4.7.1: FOR TWO PHASE FLUID (WATER AND AIR)

A total of 216 sound wave resonance tests were performed on the loop. Each test categorized a different percentage of the water and air mixture, which was tested at different speeds of the pump (RPM). According to Dr. Coward's suggestion, the air percentage ranged from 0% to 5%, in order to replicate the approximate variable range of air content within the tar sand slurry pipeline at Syncrude mines. These tests were done twice at different RPMs (3190, 2900, 2610, 2320, 2030, 1740, 1450, 1160, 870, 580, 290) by varying the frequency of the power supply to the pump at the VFD panel. Care was taken to test only on non-segregated (homogeneous) flow.

Enforcing the required constraints of non-segregated criteria, and for the different percentage of the air content, the different range of RPM of the circulating pump that would be acceptable were:

- For the 5% air content, range of 3190 down to 2610 RPM
- For the 4% air content, range of 3190 down to 2320 RPM
- For the 3% air content, range of 3190 down to 2030 RPM
- For the 2% air content, range of 3190 down to 1740 RPM
- For the 1% air content, range of 3190 down to 1740 RPM
- For the 0.8% air content, range of 3190 down to 1740 RPM
- For the 0.5% air content, range of 3190 down to 1450 RPM
- For the 0.3% air content, range of 3190 down to 1160 RPM
- For the 0.25% air content, range of 3190 down to 1160 RPM
- For the 0.2% air content, range of 3190 down to 580 RPM
- For the 0.15% air content, range of 3190 down to 290 RPM
- For the 0.1% air content, range of 3190 down to 290 RPM
- For the 0.05% air content, range of 3190 down to 290 RPM
- For the 0% air content, range of 3190 down to 290 RPM

The data was grouped according to the fixed RPM of the pump:

In order to show the discrepancies between the test results and the theoretical calculation, the theoretical expected curves and the experimental result were plotted together (Figure 4-6 to 4-17).

Each test could be considered as taken in an approximate isothermal condition. Given the time it took to record the gages for each sound wave event around the loop (1.5 minutes), the moving fluid (14 liters) only indicated one or two decimal point of degree Centigrade change.

In general, all the figures show some small discrepancies between 0.2% up to the 1% of the air content in the fluid. These could be attributed to a combination of the factors below:

1. Minor error in measurement of the mixture volume
2. Visual error in picking up the resonance condition on the scope display
3. Sensitivity effect of all the instruments involved and the gauge readings
4. Release of dissolved air due to a rise in temperatures by a few degrees during a group of tests taken in a row
5. The Pizoelectric transducer receiver had to be screwed into the side of a tee fitting, which make the receiver to be offset by about 3.5 cm from the side of pipe.
6. For the calculation purposes, it was assumed that the Pizoelectric Transducer receiver was installed on an 11 cm diameter pipe (Fig. 4-3).
7. The cross sectional of the PVC pipe would have expanded due to the varied internal pressure. The largest internal pressure numbers recorded were:

$\text{Discharge pressure} = 5.9 \text{ PSI} = 40.69 \text{ KPa}$
 $\text{Suction pressure} = 1.3 \text{ PSI} = 8.97 \text{ Kpa}$
8. Compressibility effect of the air content due to the varied internal loop pressure

Figure 4-13

Figure 4-14

Figure 4-15

Resonance Frequencies of a 1.5" PVC Pipe (Water & Air) At 290 RPM

Figure 4-16

The data also averaged at each air percentage in the fluid mixture (Figure 4-17). Again, the figure shows some small discrepancies within range of 0.2% to 1% of the air content in the fluid.

Figure 4-17

The last figure in this group summarized all the two-phase results in a single sheet (Figure 4-18). On the figure, the first Y-axis on the left was to scale the tested resonance frequencies in the 1.5 inches (3.8 cm) PVC pipeline, in Hertz. The second Y-axis on the right was to scale the corresponding RPM of the pump accordingly. The horizontal long bars across each group of the tests were to present the calculated theoretical resonance frequencies in each of the mixed fluids, according to the percentage of the air content in that fluid.

Tested Resonance Frequencies of a 1.5" PVC Pipe (Water & Air)

Figure 4-18

4.7.2: FOR THREE PHASE FLUIDS (WATER, AIR, AND SOLID)

A total of 42 sound wave tests on the loop were performed. For each test, a figure was made and the resonance frequency of the pipe was calculated and compared with the experimental result. The new total volume of the loop system was $17,910 \text{ cm}^3$ as the pump was replaced and the piping around it was modified. Each test categorizes a fixed volume of 5% Poly Ethylene beads (895.5 cm^3 , by volume). The air percentage volume for the tests was 0%, 0.05%, and 1%. These tests were done twice at different RPMs (2700, 2400, 2100, 1800, 1500, 1200, 900) by using the VFD (Variable Frequency Drive). Care was taken to test only on non-segregated moving fluid.

Because the tests were conducted on the mixtures with the three specified air contents, all that was needed was to average the resonance frequency results. That may create a single figure with three scattered points as the average of the test results. In order to show the discrepancies with the Shook's equation and other theoretical assumptions, an overlapped figure (Figure 4-19) was made out. The figure indicates some discrepancies between the tested points and the theoretical expectation:

- 1- At 0% air content, measured resonance was 1966 Hz in comparison with the expected theoretical resonance of 2203.9 Hz. The theory suggested that there was 0.016% of air volume (2.9 cm^3) within the loop.
- 2- At 0.05% air content, measured resonance was 1441 Hz in comparison with the expected theoretical resonance of 1631.2 Hz. The theory suggested that there was 0.081% of air volume (14.5 cm^3) within the loop.
- 3- At 0.1% air content, measured resonance was 1181 Hz in comparison with the expected theoretical resonance of 1352.4 Hz. The theory suggested that there was 0.15% of air volume (26.8 cm^3) within the loop.

Again each test could be considered to have been taken in an approximate isothermal condition. That was due to the volume of the loop that was about 18 liters and the time taken to record all the readings around the loop, which took about 1.5 minutes. For each reading period, the loop temperature did not have a chance to change more than one or two decimal points of a Centigrade degree.

In general, the figure shows some discrepancies between the actual readings and the theoretical expectation. Part of the problem could be caused by the air bubbles stuck to the grain beads of the Poly Ethylene (solid). It was not practically possible to eliminate fully the air bubbles.

The other possible reasons for the minor discrepancies are already listed during the test results and interpretation of the two-phase fluids.

Average Resonance Frequencies of a 1.5" PVC Pipe (Water, Air, 5%Solid) at Different Frequencies

Figure 4-19

The next figure was designed to plot the expected theoretical resonance frequencies of the 38 mm (1.5") PVC pipe with fixed solid content of 5% by volume and variable air content between 0% up to 95% (Figure 4-20). As the plot suggests, the maximum resonance frequency of such loop happens at 0% air content and is 2209.9 Hz. On the other hand, the minimum resonance frequency of the same loop happens at air content ranging from 49% to 51% and calculated to be 107.8 Hz.

Figure 4-20

The last figure in this group was created to summarize the results of all the three phases in a single sheet (Figure 4-21). On the figure, the first Y-axis was to scale the tested resonance frequency in the 1.5 inches (3.8 cm) PVC pipeline, in Hz. The second Y-axis located at right hand side of the figure, and was to scale the rated RPM of the pump accordingly. The horizontal bars across each group of the tests were to present the calculated theoretical resonance of the pipe according to the percentage of the air-content in that fluid.

Tested Resonance Frequencies of a 1.5" PVC Pipe (Water, Air, Beads)

Figure 4-21

4.8: CONCLUSION TO THE RESONANT FREQUENCY TESTS

Analysis of the results of 258 resonance tests done in this part of the experiments proved that the speed of sound equation in a multi phase slurry mixture derived by Shook (Shook, 1976) was valid.

$$1/C^2 = \rho_m [\alpha_1 / E_1 + \alpha_2 / E_2 + + D / E_p.t] \quad (E4-21)$$

However, some small discrepancies of up to 1% air content existed in the mixture. Experiments also showed that the speed of sound in the slurry was very sensitive to the amount of air content. In comparison, the speed of sound was slightly sensitive to the solid content within the slurry flow.

It was also found that the speed of sound changes the most when percentage of air content is very low (up to 1%). On line and instantaneous monitoring of air content in oil sand slurries will be a significant contribution to the science of the slurry flow in large diameter installations.

CHAPTER 5:

NOISE SPECTRUM TESTS

5.1: INTRODUCTION

Noise level spectrum of the tar sand slurry flow in the pipelines at the North Mine and Aurora Mine may be measured and recorded. The result may then be investigated to determine natural resonance frequencies of the slurry flow, which can be related to the air content in the slurry flow.

5.2: THEORETICAL DEVELOPMENT

5.2.1: SOUND LEVEL MEASUREMENT

The range of sound amplitudes is very great and it is common to express the sound pressure by the logarithmic scale, in decibels (Dowling, 1983). The sound pressure level (SPL) is a mean square level of fluctuation and is defined by convention as:

$$SPL = 20 \log_{10} \left(\frac{p'_{rms}}{0.0002 \mu bar} \right) = 10 \log_{10} \left(\frac{p'_{rms}}{p_{ref}} \right)^2 \quad (E5-1)$$

$$SPL = 20 \log_{10} \left(\frac{p'_{rms}}{2 \times 10^{-5} N / m^2} \right) = 20 \log_{10} p'_{rms} + 94$$

Where: $p'^2_{rms} = p'^2_{average}$

The international reference pressure of (2×10^{-5} Pa for airborne sound and 10^{-6} Pa for underwater sound) is average threshold of hearing by young adults when listening to a pure tone of 1000 Hz (Bell, 1982). The typical sound levels in an everyday exposure are as shown below (1 atm = 14.69595 psi = 101.325 kPa):

0 dB = 3×10^{-9} psi = 2.07×10^{-5} Pa:	Threshold of hearing
20 dB = 3×10^{-8} psi = 2.07×10^{-4} Pa:	Whisper
40 dB = 3×10^{-7} psi = 2.07×10^{-3} Pa:	Quiet residential neighborhood
60 dB = 3×10^{-6} psi = 2.07×10^{-2} Pa:	Normal speech
80 dB = 3×10^{-5} psi = 2.07×10^{-1} Pa:	Busy office
100 dB = 3×10^{-4} psi = 2.07 Pa:	Canning plant, Heavy city traffic, Subway

120 dB = 3×10^{-3} psi = 2.07×10 Pa:	Discotheque
140 dB = 3×10^{-2} psi = 2.07×10^2 Pa:	Large propeller aircraft, Air raid siren, Riveting and chipping
160 dB = 3×10^{-1} psi = 2.07×10^3 Pa:	Medium jet engine

The available instruments in the market to measure the sound level are included:

- Sound Level Meter
- Integrating Sound Level Meter (ISLM)
- Noise Dosimeter

Using the Sound Level Meter (SLM), readings in the different Octave band frequencies (spectrum) may be measured in decibel (L_n , $n = 1, 2, 3, \dots$). The total composite sound level then may be calculated by the following formula:

$$\text{Total } L = 10 \log [\sum 10^{L_n/10}] \quad (\text{E5-2})$$

$$\text{Total } L = 10 \log [10^{L_1/10} + 10^{L_2/10} + 10^{L_3/10} + \dots + 10^{L_n/10}]$$

That may be schematically denoted by (Pierce, 1981):

$$L = L_1 \oplus L_2 \oplus L_3 \oplus L_4 \oplus \dots \oplus L_n$$

For the combination of the two levels, equation (E5-1) may be used:

$$L_1 \oplus L_2 = L_2 + C_+ (L_2 - L_1) = L_2 + C_+ (\Delta L)$$

$$C_+ (\Delta L) = 10 \log (1 + 10^{\Delta L/10})$$

$C_+ (\Delta L)$ is called *decibel addition function*.

L_2 is always to be considered larger than L_1 (if needed, interchange L_2 and L_1).

So, $C_+ (\Delta L)$ is always considered for the positive values of ΔL . “For applications requiring only integer decibel accuracy, a convenient approximation is (Bell, 1982):”

$$\Delta L = 0, 1 \quad C_+ (\Delta L) = 3$$

$$\Delta L = 2, 3 \quad C_+ (\Delta L) = 2$$

$$\Delta L = 4, 5, 6, 7, 8, 9 \quad C_+ (\Delta L) = 1$$

$$\Delta L = 10 \text{ or greater} \quad C_+ (\Delta L) = 0$$

Relative response functions for A, B, and C weightings.

Figure 5-1

Decibel addition function $C_s(\Delta L)$; solid line gives function for ΔL between 0 and 16 dB; dashed lines give $10C_s(\Delta L + 10)$ and $\frac{1}{10}C_s(\Delta L - 10)$, both of which approach $C_s(\Delta L)$ in limit of large ΔL . Dots are the integer-decibel approximation to $C_s(\Delta L)$.

Figure 5-2

Based on the center frequencies, the audible Octave band measurement could only measure bands as :

16, 31.5, 63, 125, 250, 500, 1000, 2000, 4000, 8000, 16000, and 31500 Hz

As an example, in order to find out the estimated *A-weighted* sound level of an Octave band sound-pressure measurement, it may be said that:

Since the individual band components partitioned in the sound is not known, each band may be corrected for the *A-weighting* of it by using the correction amount at its center frequency (Pierce, 1981).

Center frequency in Hz	Correction for <i>A-weighting</i> in dB
31.5	-39
63	-26
125	-16
250	-9
500	-3
1000	0
2000	+1
4000	+1
8000	-1
16000	-7

In the following, solution to a couple of numerical examples is provided, because the method will be used intensively for the calculation of the slurry pipeline in this thesis later on.

Example:

Assume that the Octave-band sound pressure levels measured at a point in a factory are as tabulated below:

dB	Cent. Freq.
76	31.5
80	63
85	125
87	250
90	500
92	1000
96	2000
94	4000
94	8000
86	16000

Find out the *A-weighted* sound level in the tested area.

Solution:

The level for *A-weighting* needed to be corrected by using the correction that is related to the band center frequency. As the result (see Fig. 5-1) it may be written as:

$$\underbrace{76-39, 80-26, 85-16, 87-9, 90-3, 92-0, 96+1, 94+1, 94-1, 86-7}$$

The composite estimate then will be:

$$L_A = (37 \oplus 54) \oplus (69 \oplus 78) \oplus (87 \oplus 92) \oplus (97 \oplus 95) \oplus (93 \oplus 87)$$

$$L_A \cong [54 + C_+ (17)] \oplus [78 + C_+ (9)] \oplus [92 + C_+ (5)] \oplus [97 + C_+ (2)] \oplus [93 + C_+ (6)]$$

$$L_A \cong [54 + 0] \oplus [78 + 1] \oplus [92 + 1] \oplus [97 + 2] \oplus [93 + 1]$$

$$L_A \cong [54 \oplus 79] \oplus [93 \oplus 99] \oplus 94$$

$$L_A \cong [79 + C_+ (25)] \oplus [99 + C_+ (6)] \oplus 94$$

$$L_A \cong [79 + 0] \oplus [99 + 1] \oplus 94$$

$$L_A \cong [79 \oplus 100] \oplus 94$$

$$L_A \cong [100 + C_+ (21)] \oplus 94$$

$$L_A \cong [100 + 0] \oplus 94$$

$$L_A \cong [100 \oplus 94] \cong [100 + C_+ (6)] \cong [100 + 1] \cong 101 \text{ dB}$$

Example:

Now for the same problem if the question was to find the total sound level with no weighting effect (linear reading), then:

$$Total L = 10 \log [\sum 10^{L_n/10}]$$

$$Total L = 10 \log [10^{L_1/10} + 10^{L_2/10} + 10^{L_3/10} + \dots + 10^{L_n/10}]$$

$$L_1 = 76, L_2 = 80, L_3 = 85, L_4 = 87, L_5 = 90, L_6 = 92, L_7 = 96, L_8 = 94, L_9 = 94, L_{10} = 86$$

$$Total L = 10 \log [10^{7.6} + 10^8 + 10^{8.5} + 10^{8.7} + 10^9 + 10^{9.2} + 10^{9.6} + 10^{9.4} + 10^{9.4} + 10^{8.6}]$$

$$L_T = 10 \log [1.295^{10}]$$

$$L_T = 101.12 \text{ dB} \cong 101 \text{ dB} \cong L_A$$

Example:

The ambient background sound level in a lab measured (linear reading) at the specific frequency of 2000 Hz, and found to be 64 dB. Now if the circulating pump at the pipe loop is started up and the sound level measurement next to the loop at the same frequency (2000 Hz) is found to be 76 dB, what would the net sound level of the flow in the loop next to the pipe be?

Solution:

$$Total L = 10 \log [\sum 10^{L_n/10}]$$

$$76 = 10 \log [10^{64/10} + 10^{L_2/10}]$$

$$\log [10^{64/10} + 10^{L_2/10}] = 7.6$$

$$10^{L_2/10} = \text{antilog } 7.6 - 10^{6.4}$$

It is known by logarithm definition that if:

$$\log_p q = r \quad \text{then: } p^r = q$$

As the result:

$$L_2 = 10 \log [\text{antilog } 7.6 - 10^{6.4}]$$

$$L_2 = 75.7 \text{ dB}$$

5.2.2: SOUND POWER LEVEL MEASUREMENT

Again, due to the vast numerical ranges involved in measuring the sound powers, the logarithmic scale is in use, which condenses the range and simplifies the computation (Dowling, 1983). “By definition, sound power is the rate at which acoustical energy is radiated from a sound source, and its unit is watt (Bell, 1982).” The power level (*PWL*) of sound is also in decibels (*dB*) and given by:

$$PWL = 10 \log_{10} \left(\frac{\text{sound power output}}{10^{-12} \text{ watts}} \right) = 10 \log_{10} \left(\frac{W}{W_{ref}} \right) \quad (E5-3)$$

$$PWL = 10 \log_{10}(\text{sound power in watts}) + 120 \text{ dB}$$

On this scale, the pain threshold (*Power level = 1 Watt/m²*) is in correspondence with an intensity level of (Serway, 1982):

$$PWL = 10 \log_{10} (1/10^{-12}) = 10 \log (10^{12}) = 120 \text{ dB}$$

As an example:

PWL for a human shout is 70 dB, 1 dB is equivalent to $10^{-11.9} \text{ W/m}^2$, and 50 dB is equivalent to $10^{-7} \text{ W/m}^2 \text{ dB}$. The two have a non-linear relation (logarithmic relation)

5.2.3: BARRIER MATERIALS ON THE SOUND PATH

The sound isolating capability of a wall is called the *transmission coefficient* (τ) of that material (Bell, 1982).

$$\tau = W_t/W_i \quad (\text{E5-4})$$

Where:

W_t = sound power transmitted (watt)

W_i = sound power incident (watt)

Let's consider the relationship between the sound power, its intensity, and its pressure. It may be shown (Bell, 1982) that for a homogeneous wall and plane sound waves the transmission coefficient is (unit less):

$$\tau(\theta) = \frac{I_t}{I_i} = \frac{|P_t|^2}{|P_i|^2} = \left\{ \left[1 + \eta \left(\frac{\omega \rho_s}{2 \rho c} \cos \theta \right) \left(\frac{\omega^2 B}{c^4 \rho_s} \sin^4 \theta \right) \right]^2 + \left[\left(\frac{\omega \rho_s}{2 \rho c} \cos \theta \right) \left(1 - \frac{\omega^2 B}{c^4 \rho_s} \sin^4 \theta \right) \right]^2 \right\}^{-1}$$

Where in the above equation (E5-5):

I_t : Sound intensity transmitted (W/m^2)

I_i : Sound intensity incident (W/m^2)

P_t : Sound pressure transmitted (Pa)

P_i : Sound pressure incident (Pa)

θ : Angle of incident (radian)

η : Composite plate loss factor (unit less)

ρ_s : Plate surface density (kg/m^2)

B : Plate bending stiffness per unit width (N/m)

ρ : Density of medium (kg/m^3)

c : Speed of sound in medium (m/s)

The equation above is not very useful, because it depends on the incident angle. In order to convert that into a more consistent and practical form, a logarithmic term called the transmission loss (TL) was defined as:

$$TL = 10 \log 1/\tau \quad [\text{dB}] \quad (\text{E5-6})$$

Where “ τ ” is the transmission coefficient averaged over all angles of incidence.

By substituting equation (E5-6) in (E5-5) and assuming that the term:

$$\omega^2 B/c^4 \rho \ll 1$$

The transmission loss may be approximated over a wide range of usefulness as:

$$TL \approx 10 \log \left[1 + \left(\frac{\omega \rho_s}{2 \rho c} \cos \theta \right)^2 \right] \quad [\text{dB}] \quad (\text{E5-7})$$

Equation (E5-7) is called the *limp-wall law transmission loss*, as its only characteristic involved is the surface mass of the wall. Note that for $\theta = 0^\circ$ (sound impinging at normal incidence to the wall), TL is the largest and for $\theta = 90^\circ$ (at grazing incidence), TL reduces to zero.

In practice, the sound wave is incident over a wide range of angles. The averaging of equation (B5-7) ends up as (Bell, 1982):

$$TL = 20 \log (f) + 20 \log (W) - C \quad [\text{dB}] \quad (\text{E5-8})$$

Where:

f : Frequency (Hz)

W : Surface density ($\text{kg/m}^2/\text{cm}$, thickness or $\text{lb/ft}^2/\text{in}$, thickness)

For steel pipe: 78.4 in metric and 18.5 in imperial system

For clear PVC pipe: 14 in metric and 3.3 in imperial system

Density of the clear PVC is 1400 kg/m^3 (Johnson)

C : Coefficient 47 if W is in ($\text{kg/m}^2/\text{cm}$)

C : Coefficient 33 if W is in ($\text{lb/ft}^2/\text{in}$)

Example:

What would be the transmission loss of a sound within a clear PVC pipe at 125 Hz and 82 dB incidences, when measured next to the pipe wall outside? The thickness of the pipe wall is 3.68 mm.

Solution:

$$t = 0.368 \text{ cm} \quad W = 14 * 0.368 = 5.15 \text{ kg/m}^2/\text{cm thickness}$$

$$TL = 20 \log (f) + 20 \log (W) - C$$

$$TL = 20 \log (125) + 20 \log (5.15) - 47$$

$$TL = 9.2 \text{ dB}$$

So, the expected sound level measured next to the PVC pipe would be:

$$82 - 9.2 = 72.8 \text{ dB}$$

Some steel pipe specification tables (7-1, 7-2) are made available at the beginning of Chapter 7: Appendix, page 103. The data is at its original form (imperial units).

5.2.4: RESONANCE ACROSS A PIPE

At the first resonance mode (also called fundamental mode), the wavelength is twice the length of the pipe diameter (Serway, 1982).

Figure 5-3: First resonance mode across a pipe's diameter

That means, twice the diameter travel is equal to the wavelength.

$$\lambda_1 = 2D$$

$$f_1 = C / \lambda_1 = C / 2D$$

At the second resonance mode, the wavelength is equal to the diameter travel of the pipe.

That means, twice the diameter is equal to twice the wavelength.

$$2\lambda_2 = 2D$$

$$\lambda_2 = D$$

$$f_2 = C / \lambda_2 = C / D$$

$$f_2 = 2f_1$$

At the third resonance mode, the wavelength is equal to the 2/3-diameter travel of the pipe. That means, twice the diameter is equal to three times the wavelength.

$$3\lambda_3 = 2D$$

$$\lambda_3 = 2/3 D$$

$$f_3 = C / \lambda_3 = 3C / 2D$$

$$f_3 = 3f_1$$

5.3: METHODOLOGY AND RESEARCH OBJECTIVES

Moving slurry within the pipeline generates a natural audible noise spectrum. If the spectrum was measured, recorded, figure illustrated, and investigated, some resonance frequencies of the flow noise may be identified and could be linked to the amount of air content in the slurry.

5.4: APPROACH

A decision was made to do a pilot test and measurement in the lab first. The results were to help set up the measurement method and tool in order to do the same at the slurry pipelines in the Syncrude mine sites.

The available sound level measurement was an ambient Sound Level Meter (SLM). Having the PVC test loop pump shut, the ambient sound level spectrum at the test table in the pilot plant was measured. The next task was to measure the sound level with the tip of the meter touching the PVC loop, once its pump was running. The measured sound level spectrum was the combined sum of pipe noise plus the ambient noise. When the ambient noise was taken out mathematically, the result was to be the pipe noise level spectrum that existed next to the outside pipe. Finally, in order to determine what the noise level was in the pipe, the sound level transmission loss that occurred through the wall of the PVC pipe was added up. The measurement data and its related calculation and figures are skipped here to avoid repetition. The same method was used at the mine sites.

At the mine sites, similar sound level measurements were conducted. In order to show the possible difference in the pipe readings, the separate measurement at the bottom, the side, and the top of the pipelines were made. To account for the sound level transmission loss, the pipe wall material (standard steel) and thickness were considered for the purposes of calculation.

5.5: NOISE LEVEL MEASUREMENT OF THE SLURRY PIPELINES AT SYNCRUDE MINE SITES

5.5.1: PIPE MEASUREMENT POSITIONS

At North Mine site, eight sets of measurement were made and recorded for each of the following positions: The side (3 o'clock position) and top (12 o'clock position) of the 27" pipeline. It was not practical to conduct the measurement at the bottom (6 o'clock position) of the pipeline because there wasn't a right location found to do so. At the Aurora Mine, five sets of measurement were done and recorded for the bottom, the side, and the top of the 30" pipeline.

Figure 5-4: Measurement points on the pipeline

5.5.2: MEASUREMENTS AT NORTH MINE

The main pumping station was located down the north mine pit. There were two slurry pipelines each made from standard 27" diameters standard steel pipe. They ran parallel to each other at about 30 cm apart, with overall length of 4.8 Km. Each line was equipped with two Warman centrifugal pump in series of 2500 HP each, at the start point (pumping station). At a point 1.2 Km down the line, a booster pump station is located. Again, two centrifugal pumps of 2500 HP each in series boost up the flow in each line. According to the control room operator, the normal operating pressure of each pipeline may vary between 770 to 900 kPa (max. 1300 kPa), the density of the tar sand slurry may be somewhere between 1.46 to 1.49 (max. 1.6), and its temperature between 56 to 70 degree centigrade. The normal pumping capacity was about 4400 to 4700 tons/hr (max. 6650 tons/hr).

On the days that the measurement (April 24 & 25th, 2001) took place a spot was picked about 150 meters downstream from the booster pump station, which was located slightly up the hill. The spot was also about 30 meters away from a hauling road, and five meters blow it. The weather was partly cloudy but very windy, gusting up to 60 Km/hr. On the first couple of ambient sound level measurements, it was noticed that the wind effect was causing a higher decibel reading. In order to correct that to some extent, a large cardboard box was backed up to a dirt pile and to the wind, was used to block the direct blast of the wind. The meter then was held in the large opening of the box for the ambient noise measurement. The other factor that had some effect on the measurement was the fact that two pipelines ran parallel to each other and were separated only by 30 cm apart. For the top measurement, the instrument could have picked up some combined noise from both pipeline simultaneously.

A set of eight sound level measurements of the ambient noise, the pipeline side, and the pipeline top were taken. The instrument setting for all sound level measurement was as follows:

- Range: From 12.5 Hz to 20 kHz
- Time mode: 1/3 Octave band filter set
- Response: Slow
- Weighting: Linear
- Mode: SPL (Sound Pressure Level)
- dB Range (sensitivity): 60 to 120 dB

On auto run mode, the SLM instrument scans for about 10 seconds on each range frequency. At the end of each run, the saved data may be downloaded in the Hyperterminal program in a laptop. Later on, the data can be imported into the Excel spreadsheet and processed.

There was no suitable spot found at the site, to place the sound level meter beneath the pipeline, in order to take the bottom readings. The individual readings and its related figure may be found in the Appendix. In the following, only the figure presenting the average of each group is presented.

Average Ambient Sound Level Spectrum, North Mine

FREQ(Hz)	LEQ(dB)	MAX(dB)	MIN(dB)	SEL(dB)
12.5	78.0	83.4	69.9	88.1
16	76.0	80.9	69.7	86.1
20	77.9	84.0	69.2	87.9
25	72.5	77.7	65.7	82.6

Figure 5-

5.5.3: MEASUREMENTS AT AURORA MINE

Both the main pumping station and the booster station are located on flat land and are about 1.2 km apart. The single slurry pipeline (train) in operation was constructed from the standard 30" diameter steel pipe. Each station has two centrifugal pumps in series, 2500 HP each. According to its operator, the operating pressure of the pipeline was at 7300 kPa, with the average density of the slurry at about 1.5, and its temperature at 30 degree centigrade.

On the day the measurement took place (April 26, 2001), a spot was picked about 100 meters downstream from the booster pump station, on a flat run next to an expansion joint. The local weather was sunny and calm. A set of five sound level measurements were taken from the ambient, the bottom, the side, and the top of the pipeline. The individual readings and its figure may be found in the Appendix. In the following, only the figure presenting the average of each group is presented.

Table 5-7

Average Net Inside Pipeline Sound Level Spectrum (top) of Slurry Flow at Aurora 30"
Line

Figure 5-

Several times the external noise level spectrum of the slurry pipelines at North Mine and Aurora Mine in Forth McMurray were measured, and presented above. Based on those results, the internal noise of each pipe was calculated. By analyzing the internal noise spectrum, which is the slurry's flow signature, it would be possible to estimate its air content.

5.6: PIPELINE MEASUREMENT METHODOLOGIES AND APPROACH

As mentioned in section "B" above, in addition to the ambient noise measurements, the SLM instrument at North Mine and Aurora Mine sites also recorded the noise level spectrum of the tar sand hydrotransport pipelines. Plotting and searching the spectrums may reveal the resonance frequencies of the slurry pipeline that could be related to the air (gas) content of the slurry.

5.7: MEASUREMENT CONDITION

At North Mine, eight-noise measurement sets for each position of the side (3 o'clock) and top (12 o'clock) positions of the 27" pipeline were taken. It was not practical to conduct measurement for the bottom (6 o'clock position) of the pipeline because there was no right location to do so. At the Aurora Mine, a set of five noise measurements were taken from the bottom, the side, and the top positions of the 30" pipeline.

5.8: SEARCHING THE MEASUREMENT RESULTS FOR RESONANCE

From this point on, for an example, samples from the measurement of side position at the 27" pipeline at North Mine will be analyzed, and discussed. The model can be applied to the sets of measurements with results provided in the Appendix.

5.8.1: THEORETICAL RESONANCE and SPEED of SOUND ACROSS THE 27" PIPELINE

The specifics of the 27" standard steel pipe is given as:

Diameter = 0.6588 meter

Wall thickness = 0.009525 meter

In average, the main components of the slurry by volume were taken as:

Bitumen: 9%

Sand (quartz): 36%

The subtotal counts for 45% and the rest (55%) would be mostly water, with a few percentages of air or gas in it. Note that sand content sizes up to only a few microns with the probability of 90%. Most of the larger sand particles crush against each other during the hydrotransportation and break down to smaller pieces continuously.

For physical properties of the materials, the data given at table 4-2 may be used. Speed of sound in the pipeline may be calculated by using the Shook's equation (E4-2).

$$1/C^2 = (\rho_a \alpha_a + \rho_q \alpha_q + \rho_b \alpha_b + \rho_w \alpha_w) [\alpha_a / B_a + \alpha_q / B_q + \alpha_b / B_b + \alpha_w / B_w + D / E_s t]$$

ρ : Density, Kg/m³

α : Volumetric proportion

- D:** Pipe outer diameter, m
t: Wall thickness, m
B: Bulk modulus of material, Pa
E_s: Elastic modulus of pipe, Pa

The subscript letters refers to:

- a:** Air
q: Quartz (sand)
b: Bitumen
w: Water

The expected air content by volume was less than 5% per Dr. Julian Coward's previous experiments. So the spreadsheet may be arranged for up to 5% of the air content. The results may be graphed as in the following figure:

Theoretical Resonance Frequency and Speed of Sound Across 27" Slurry Pipeline
at North Mine

Figure 5-

In the figures for measurement experiments, the sound level was plotted with respect to the frequency spectrum. Finding or assuming a resonance frequency led to calculate the related speed of sound for it. The total water and air content in one volume unit of slurry was to be 0.55, which means ($\alpha_a + \alpha_w = 0.55$). The unknown variables of Shook's equation were reduced to one unknown, which was air content volume (α_a), this may be solved easily. It was expected to have a low percentage of air (within 5% range) in the slurry. Then first resonance may be chosen in the range of 31.5 Hz (which corresponds to 5.99% air content) to 100 Hz (which corresponds to 0.56%) as a reasonable assumption. Knowing the first resonance range upper limit is to be 100 Hz, makes one certain that the upper limit for second and the third resonance range would be 200 and 300 Hz respectively.

In the following page, the first experimental figure for sound level measurement for the side position of 27" tar sand slurry pipeline at North Mine, is displayed as a sample. The bumps on the SEL curves may be checked and considered as possible resonance frequencies.

Figure 5.12

These readings then may be grouped into the first, second, and third resonance ranges that have been set up already. The results for the eight-spectrum measurement taken at North Mine would be displayed in the next page.

Table 5-8: Resonance searching of 27" pipeline (side), North Mine

Through a calculation method similar to one used before, selected resonance frequencies in the table above will yield to the following air content values as tabulated below:

The different harmonics of resonance frequencies may be grouped to its equivalent first harmonic as follows:

C	$\alpha_{c,1}$	Hz	f_1	f_3	f_5	Repealed f	f	Test freq	ResoFreq	Repeated f
41.5	0.0599	31.5	2			2	31.5	31.5	31.5	2
52.7	0.0365	40	3			3	40.0	40	40	3
65.9	0.0231	50	3			3	50.0	50	50	3
83.0	0.0144	63	2			2	63.0	63	63	4
87.8	0.0128	125		2		2	62.5			
105.4	0.0089	80	2			2	80.0	80	80	11
105.4	0.0089	160		4		4	80			
109.8	0.0082	250			5	5	83.3			
131.8	0.0056	100	1			1	100.0	100	100	3
131.8	0.0056	200		2		2	100			

Table 5-10: Resonance grouping of 27” pipeline (side), North Mine

By plotting “Speed of sound” versus “Air Content (vol.%)” with a second Y-axis to show the “Repeated Resonance Frequencies” the following figure was produced:

Figure 5-

5.9: CONCLUSION TO THE SECOND APPROACH

The above figure indicates that for test involving the side position of pipeline, most frequent resonance (11 times) occurred at frequency of 80Hz. This corresponds to 0.89% of air content in the slurry flow tested. The figure will not suggest that as a fixed number, because the mixture ratios and blends change continuously. Then, again the test results may vary at different locations along the pipeline. The above non-invasive method serves to present a scientific technique to estimate the air content in the slurry pipeline, based on listening to the audible sound level (noise) spectrum of its flow.

CHAPTER 6:

OVERALL CONCLUSION TO THE THESIS

The test methods presented in this thesis have demonstrated some scientific technique for estimating air content in the slurry. This technique can lead to the measurement of audible sound speed, and audible sound resonance within the pipeline. These methods could be used to develop an instrument to serve as a tool for instantaneous monitoring and on-line measurement of the slurry air content. The tools will assist the slurry pipeline handlers to measure and maintain the optimum air content of the tar sand slurry. This is needed to provide for good bitumen recovery, corrosion monitoring of the pipeline, as well as for achieving a more efficient pump performance in commercial oil sand hydrotransport pipeline.

Specification of the Instruments Used

- Field FFT, Fast Fourier Transform Analyzer (scope & printer), ONO SOKKI, CF-200
- Tektronix TDS 3012 (oscilloscope), DPO, 100 MHz, 1.25 GS/S
- Tiwatsu SS-5705 (oscilloscope), 40 kHz
- Amplifier: Optimus, 50 Watt, XL-50
- Omega Scientific E & L Instrument, 2001 Function Generator (square, saw blade, sine wave), range 0 to 100 kHz
- DC generator, Xantrex, Model HPD 30-10 SMSA
- Kistler series (211B5) Piezotron pressure transducers Quest Electronics Model 1800, Precision Impulse Integrating Sound Level Meter

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #1

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #2

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #3

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #4

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #5

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #6

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #7

Sound Level Spectrum of 27" Slurry Pipeline
(side + ambient) at North Mine, Test #8

Side pipeline sound level due to slurry flow
North Mine
